

Improvements on Drinking Water (surface and ground) Quality

Raafat A. Mandour

Toxicology Unit, Emergency Hospital, Mansoura University, Egypt

Abstract

Background; Drinking water has received considerable attention recently. However, misuse and mismanagement have resulted in a rapid and widespread decline in source-water quality and supply. Water quality guidelines can be used to identify constituents of concern in water, to determine the levels to which the constituents of water must be treated for drinking purposes. Membrane technology for the water cycle is playing an important role in the provision of safe water supply and treatment.

The aim of this paper is to conduct chemical and microbiological analysis of water samples..

Materials and Methods; Forty three samples representing different types of drinking water (surface and ground) from different districts of Dakahlia governorate were subjected for analysis chemically and microbiologically. Heavy metals were measured by atomic absorption spectrophotometer

The results revealed that there were several areas polluted chemically by some heavy metals (Ni, Cd, Pb, Mn and Fe) and microbiologically by (Entamoeba Histolytica, Amoeba, Egg of Nematodes and total count of Bacteria).

Conclusions and Recommendations; water treatment could see better membranes with both higher permeability and tighter cutoff. Removal of some chemical constituents must be done and sewage system projects are implemented in all polluted areas of towns and villages.

KEYWORDS: Water quality; Guidelines; Membranes.

1. Introduction

From a socio-economic standpoint, increasing water resources by reuse can strengthen the infrastructure of a country and improve the lives of its people. We have been facing increasing problems due to the pollution of the surface and underground water. Due to the geography and climate variations around the world, approximately 70% of the renewable water resources are unavailable for human.^[1, 2] Lack of a sufficient quantity of water suitable for irrigation and drinking can lead to food shortages and health concerns for millions. Consequently, there is an urgent need to increase water. The standard reverse osmosis (RO) membrane is a thin film composite (TFC) and its introduction in the late 1970s was a major advance in membrane preparation resulting in greatly improved permeability and retention. Recently, there have been new developments involving thin film nano-composite reverse osmosis (TFNRO).^[3]

Powdered limestone is effective in removing Pb^{2+} ions from aqueous solutions, tap water and natural water samples. It is an inorganic sorbent which abundant in nature, low in cost and have minimal environmental impact for restoration or remediation of natural resources. Moreover, the recommended procedure was successfully applied to some natural water samples and was nearly free from interferences of some selected foreign.^[4]

The aim of this work is to conduct chemical and microbiological analysis of water samples.

2. Materials and Methods

All samples were manually collected in two liter polyethylene bottles for chemical analysis and in one sterile liter glass bottle for microbiological analysis using the procedure described in the standard methods for the examination of water.^[5] Forty three samples

representing different types of drinking water (surface and ground) from different districts of Dakahlia governorate, Fig (1).

The water samples were selected according to the specific objectives of the study. Heavy metals were measured by atomic absorption spectrophotometer (AAS) Buck Scientific Company, USA in the lab of Genetic Engineering and Biotechnology Unit Mansoura University.

2.1. Microbiological analysis

From the public health point of view, the coli form bacilli with some of pathogenic bacteria are the most important microbes to be investigated. This is done as follows:

2.1.1. Total count of Bacteria

The total count of bacteria for each water sample is done by poured plate method. This must not exceed 50 cell / ml at 37 C⁰ for 24 hours or at 22 C⁰ for 48 hours.

2.1.2. Total Coli form

The term total coli form, refers to rod shaped, non-spore-forming bacteria. The coli form group bacteria are capable of producing acid and gas from lactose in a suitable culture medium using Macon key Broth at 35 to 37 C⁰. It is customary to report results as Most Probable No (MPN). The MPN is not an exact enumeration, but a high probability estimate of a coli form count per 100 ml of water. These counts are reported as MPN/ 100 ml. The water sample must not exceed than 3 cell / 100 ml according to Egyptian Ministry of health (EMH).^[6]

2.1.3. Biological analysis

Microscopic examination for living microorganisms (protozoa, bluish green algae) is made without any treatment. Few drops of water samples are put on a glass slide and examined by light microscope using high power.

3. Results

Table (1) represents the chemical results of polluted drinking water samples by some heavy metals which exceed than the permissible limits of World health organization (WHO)^[7] and EMH.^[6] Table (2) shows the microbiological contamination in most of the studied drinking water samples.

4. Discussions

A large part of research is directed towards source-water contaminants and their treatment. The objective of this work is to conduct chemical and microbiological analysis of water samples. Table (1) shows the values of detected heavy metals such as Cd, Ni, Pb, Mn and Fe in some of the studied samples, higher than the permissible limits of WHO^[7] and EMH.^[6] This might be due to discharge domestic wastewater of many villages which lies on the two sides of the two branches of Nile. Also, these two branches receive through distributaries canals, the agricultural wastes such as pesticides, fertilizers and other residues. Removal of iron and manganese was done by passing air through drawing raw water from product wells via centrifugal pumps due to oxidation of iron and manganese ions by aeration compressor. Adjust pH by adding potassium permanganate and sodium hydroxide before reaching the cemented aeration tank. Thirty minutes is the time of collected water in cemented aeration tank. Pressure sand filters were used for retention of the resulted sediments in sedimentation tank and then chlorinate the pure water before reaching to the network, Fig. (2). Treatment units must be prevailed as we suggested before, through the polluted areas by iron and manganese, not only in one place like samples numbered 17 and 18 in Table (1). It is noted that the water treatment of both well No 17, Mit-Ghamr district has improved the contents of Fe and Mn in drinking water, by decreasing its values distinctly from 0.49 and 0.45 ppm to 0.001 and 0.003 ppm respectively.

Table (2) shows the polluted drinking water samples by micro-organisms (bacteria, coli form, bluish green algae and protozoa) exceed than the permissible limits of EMH.^[6] The risks

from chemical pollution of water are on a small scale compared with the hazards from microbial contamination of drinking water. Among 20 to 30 different infective diseases may be affected by change in water supply. Many of this water related diseases depend on facial access to domestic water sources. The chain transmission may be broken by safe disposal of feces as well as by protection of the water supplies. It is important to mention that bacteria may survive for more than six months in proper subsurface.^[8] Most of the area of study has no sewage system. Many people use septic tanks without any cautions for preventing the water from contamination. Also, disposal sites and open drains in which the wastes usually disposed are present extensively in the area. According to WHO^[7] and EMH^[6] standard limits for drinking, the drinking water must not contain any bacteria. The differentiation of the microbial load might be attributed to the volume, the type and the source of pollution of the water sources. Thus, the drinking water must be treated against microbiological pollution before it is distribution to consumers. Also, it is very important to prevent different sources of microorganism from reaching the drinking water. Sewage system projects are implemented in all towns and villages. Potential pretreatment strategies include inactivation by advanced oxidation, such as UV? The addition of bio-film signaling agents that either disperse or interfere with quorum.^[9] In water treatment, the contaminants are typically pathogens, colloids non organic materials and in some cases trace organic compounds (natural and synthetic).

Low pressure membranes are playing a major role in water treatment. There is a need to improve retention at the same or higher water permeability, and this has been achieved by 'stretched pore',^[10] where the elongated pores achieve higher permeability along with lower molecular weight cutoff. Water reclamation by RO could be assisted by improved bio-fouling control strategies under development. Guidelines are values set for specific parameters based on studies and field observations that typically represent the upper limit of safe for the use. No single set of water quality guidelines is universally applicable. Many factors, including the level of technology, economic status, relative associated risk, and field conditions, influence the variability of guidelines among nations.^{[11], [12] and [13]} RO is now the predominant method of desalting. Membrane distillation (MD) is a thermally driven membrane process which has the benefit of ambient pressure and the ability to operate at very high salinity⁵ so that overall recoveries > 80% may be feasible, possibly involving MD crystallization.^[14]

5. Conclusions

The polluted areas are due to percolation of the drainage liquid wastes to the groundwater. Water treatment could see better membranes with both higher permeability and tighter cutoff.

6. Recommendations

The results obtained through the study made on the different types of water through Dakahlia Governorate, it is recommended that:

- 1- Full flushed water for one to two minutes before drinking and cooking.
- 2- Using household filter (with replaceable cartridges) which contain granular activated carbon as an adsorbent, where the adsorption is a major step in making drinking water more pleasant by reducing objectionable tastes, odors, colors and sediments.
- 3- Chemical and microbiological analyses must be carried-out periodically for the surface and groundwater to ensure the water suitability.
- 4- Excess of Mn & Fe could be treated through, oxidation process through addition of air, chlorine, potassium permanganate, or ozone, followed by filtration.
- 5-Chlorination is intended to protect the distribution pipe work and to prevent the growth of bacteria respectively.
- 6- The water well should be located at safe distance from all possible sources of contamination.
